## Abstract

This paper assumes that the government sponsored enterprises (GSEs, Fannie Mae and Freddie Mac) are unsustainable—the expected costs they create for U.S. taxpayers far exceed their expected benefits. The question addressed is then how to reorganize the U.S. mortgage market in the absence of GSEs. The paper evaluates a specific mortgage market reform proposal to abolish the GSEs and substitute private market incentives for mortgage originators, securitizers, and investors, while retaining the FHA and HUD programs in support of lower-income and first-time homebuyers. The paper assembles data showing that stable housing and mortgage activity can be sustained with minimal governmental intervention, including data that demonstrate the success of European housing and mortgage markets that operate with little government intervention.

# Reforming the U.S. Mortgage Market Through Private Market Incentives

By Dwight M. Jaffee

## **1. Introduction**

For almost 40 years, Fannie Mae and Freddie Mac dominated the U.S. mortgage market based on their status as government sponsored enterprises (GSEs). At their 2003 peak, before the explosive growth in subprime mortgages, the two GSEs owned or guaranteed mortgages and mortgage-backed securities (MBS) representing over 50% of the country's home mortgages, while issuing debt and MBS guarantee obligations totaling \$3.8 trillion (Federal Housing Finance Agency (2009)). By 2008, however, the U.S. mortgage and housing markets had crashed, and the two GSEs survived only as the result of a government bailout and conservatorship; see Jaffee (2010b). At year-end 2009, the GSE's total debt and MBS obligations had reached \$5.5 trillion and the taxpayer costs of the GSE bailout could well reach \$400 billion (GAO (2009)).

Although the subprime crash devastated the GSEs, their dominance of the U.S. mortgage market has actually expanded: during 2009 more than 70 percent of mortgage market activity was carried out through the GSEs and another 25 percent was guaranteed through the FHA and VA government programs; see Inside Mortgage Finance (2010). This expanded government role reflects the intense use of the GSEs and FHA/GNMA as policy instruments to revive the mortgage market.<sup>1</sup> Some commentators even suggest that a private market for U.S. mortgages is no longer possible. The more accurate description, however, is that most private mortgage

---

<sup>1</sup> The Federal Housing Administration (FHA) and Government National Mortgage Association (GNMA) reside within the Department of Housing and Urban Development (HUD) and provide direct support for the mortgage market. There are also many indirect mortgage and housing policies, the quantitatively most important of which is the federal tax deductibility of household mortgage interest payments. See Jaffee and Quigley (2007, 2010) for surveys of the full range of government programs in support of the U.S. housing and mortgage markets.

market activity has been crowded out by the now heavily subsidized government programs.

The goal of this paper is to look beyond the current crisis and to analyze proposals for the long-term reform of the U.S. mortgage market. Following the structure of this volume, it is assumed the GSEs are abolished and play no further role as government sponsored enterprises within the U.S. mortgage market.<sup>2</sup> The analysis focuses on my specific proposal to reform the U.S. mortgage market by applying purely private market incentives for mortgage originators, securitizers, and investors, while retaining the FHA and HUD programs in support of lower-income, first-time, and other special classes of homebuyers.<sup>3</sup> The analysis develops the case that private incentives and institutions are sufficient to create a functional and efficient mortgage market, while eliminating the need for taxpayer subsidies and bailouts. The discussion marshals the evidence that stable housing and mortgage activity can be sustained with minimal governmental intervention, including data demonstrating the success in Western European housing and mortgage markets. The discussion concludes with an evaluation of alternative proposals to reform the U.S. mortgage market.

## **2. Reforming the U.S. Mortgage Market Without GSEs**

Reform of the U.S. mortgage market continues to be a critical policy issue, especially given that the Dodd-Frank 2010 financial reform act took no significant action in this regard. The proposal evaluated in this section is to reorganize the U.S. mortgage markets with private market incentives and institutions substituting for the GSEs. Success will be achieved if the private markets create stable and accessible mortgage credit for U.S. borrowers without requiring taxpayer subsidies or bailouts.

---

<sup>2</sup> Fannie Mae and Freddie Mac would not be the first government sponsored enterprises to lose their GSE status. Sallie Mae, the GSE supporting the student loan market, was successfully privatized in 1996; see Lea (2006).

<sup>3</sup> I include here a variety of programs in support of multifamily housing for which the GSEs played a leading role. For more details on these programs, see Ellen, Tye, and Willis (2010).

## **2.A A Proposal to Reform the U.S. Mortgage Market on Private Market Principles**<sup>4</sup>

The proposal advocated here would be implemented with just two actions:

1) Reduce the conforming loan limit—the maximum loan the GSEs may acquire or guarantee—by a fixed amount each year until the limit reaches zero and GSE activity disappears. If the conforming loan limit were reduced by \$100,000 per year, it will reach zero in approximately 7 years. This is also the average duration of a U.S. mortgage, so most of the GSEs' on-balance sheet mortgage portfolios would run off by that time as well. Steadily reducing the conforming limit has three further advantages:

- i) It provides an orderly and smooth transition. In particular, private market lenders and investors will know the GSE domain is shrinking, and should be ready to substitute for it.
- ii) The substitution of private market activity for the GSEs would be observable. If it were failing to occur, alternative actions could be taken—see point (2) below.
- iii) The GSE subsidy is removed first from the largest mortgages, thus maintaining the GSE benefit as long as possible for lower-income borrowers.

2) The existing FHA, VA, and HUD programs supporting lower-income remain active under this proposal. These programs will thus provide a safety net were the private market system to fail to satisfy borrower needs as the GSEs retrench. These programs would also be available were a future financial crisis to require new, temporary, government support of the mortgage market.

GSE activity could also be reduced by requiring the GSEs to steadily raise their guarantee fees until they are priced out of the market; see Glaeser and Jaffee (2006), Glaeser (2010), and Jaffee (2010a). This device could substitute for, or expand on, the proposal to reduce the conforming loan limits. The discussion here focuses on the proposal to reduce the conforming loan size because it is simple and readily verifiable.

---

<sup>4</sup> This was first described in my [Wall Street Journal](#) Op-Ed of October 25, 2010, Jaffee (2010a).

## **2.B The Functional Structure of the U.S. Mortgage Market**

To create accessible credit, a mortgage market must coordinate three basic functions:

- (1) originate new mortgages,
- (2) design mortgage contracts and set underwriting standards, and
- (2) place the originated mortgages with long-term investors.

In this section, I discuss how these activities are currently carried out and provide introductory comments on how they might change under a private mortgage market.

### **2.B.1 The Mortgage Origination Function**

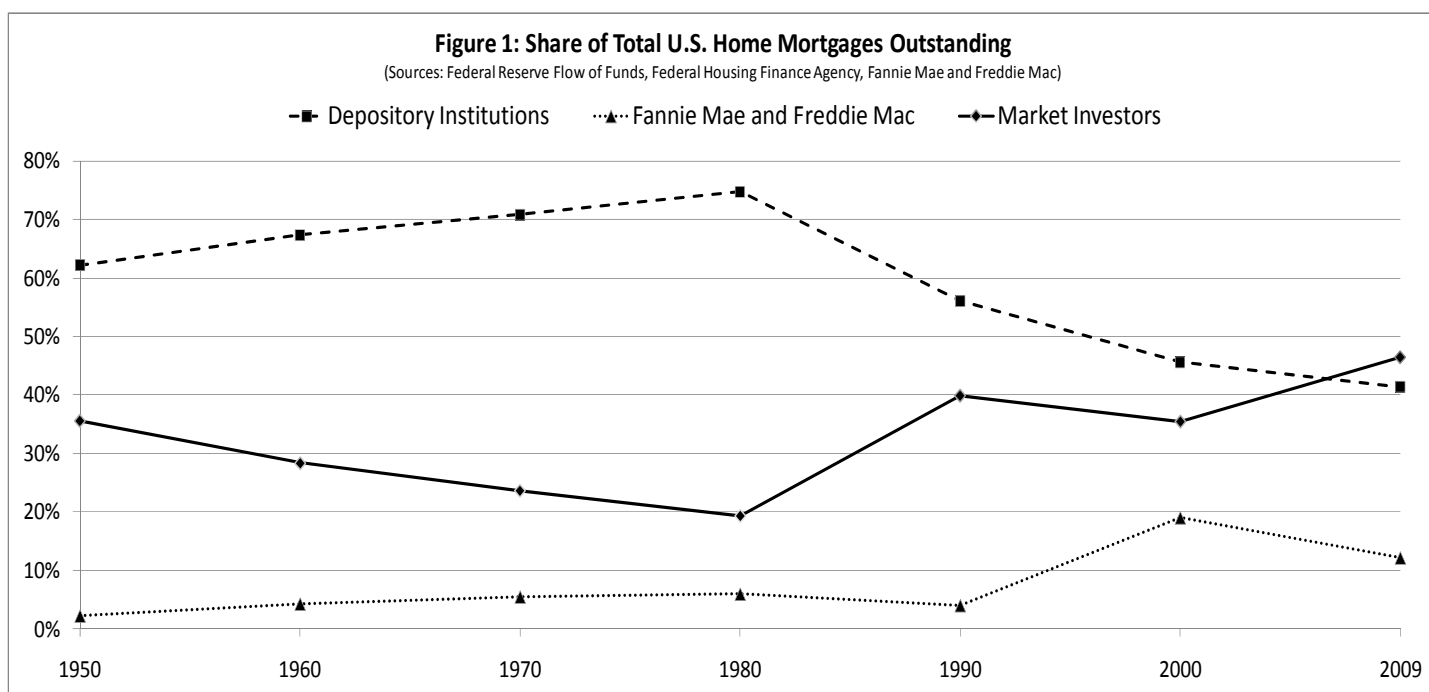

The mortgage origination function in the U.S. has always been carried out entirely by private firms, even in the presence of the GSEs and the government's FHA and VA programs. In fact, the GSE charters prohibit them from originating mortgages, and the FHA and VA programs only insure mortgages that are originated to their specifications by private market firms. The termination of the GSEs thus has no direct impact on which firms will originate U.S. mortgages.

### **2.B.2 Mortgage Design and Underwriting Standards**

The GSEs always set the contract design and underwriting standards for the loans they acquired.<sup>5</sup> In the reformed system, the contract design and standards will be set by the private market alone. Since mortgages will be originated only if there are willing final investors, it is these investors who will really set the designs and standards. Given that a significant share of all U.S. mortgage originations have always been placed outside the GSEs, the change is more of a degree than of a kind. Specifically, I will argue below that, as the private market replaces the GSEs, mortgage choice will expand and the overall underwriting standards for the U.S. mortgages are likely to rise significantly (i.e. mortgages will generally be safer).

---

<sup>5</sup> Over time, this standard became automated as part of the computer software maintained by both GSEs, called *Loan Prospector* by Freddie Mac and *Desktop Originator and Underwriter* by Fannie Mae. Using this software, a mortgage originator would know if a GSE would accept a specific pool of mortgages.

### **2.B.3 The Mortgage Investment Function**

The third fundamental mortgage market function is to place the originated mortgages with long-term investors. Figure 1 shows the percentage of all U.S. home mortgages held by the three primary investor categories—depository institutions, market investors, and the GSEs—at the end of each decade as available over the last 60 years. 2009 represents the most recently available year-end data, and also represents the last year before the GSEs became government-dominated under their Conservatorship. The figure is unique in that it integrates investor holdings of home mortgages as either whole mortgages or MBS and then computes the respective market shares as a percentage of total home mortgages outstanding.

Between 1950 and 1980, the depository institutions (commercial banks, thrift institutions, and credit unions) held the vast majority of home mortgages, and almost entirely as whole

mortgages. The depository institutions were also the primary originators of home mortgages.<sup>6</sup>

The depository institutions thus combined the activities of origination and investing: this “make them and hold them” model completely dominated the U.S. mortgage market through 1970.

Several major events occurred in the U.S. mortgage markets about 1970:

- 1) In 1968, the GNMA government agency was created within HUD to issue the first modern mortgage-backed security (MBS). GNMA only securitizes FHA and VA mortgages.
- 2) Also in 1968, Fannie Mae was transformed from a government office within HUD into the public/private hybrid of a government sponsored enterprise (GSE).
- 3) In 1970, Freddie Mac was created as a second GSE.<sup>7</sup>

The three events initiated the mortgage securitization that has dominated the U.S. mortgage markets ever since. Following the prototype created by GNMA, Freddie Mac quickly added its own brand of MBS, and by the early 1980s Fannie Mae was also issuing its own MBS. Only the GNMA MBS had an official government guarantee against losses from borrower default, but the Fannie and Freddie MBS traded as if there were a strong, albeit implicit, government guarantee; indeed the three sets of MBS became collectively known as “agency” MBS. As the last step, by the mid-1980s, private market firms were creating their own MBS brands, known as Private Label Securities (PLS). Because these securities had no government guarantee of any form, they applied the innovation of structured finance, whereby the default risk was allocated differentially across the various tranche, with the senior tranche protected by the subordinated junior tranche.

---

<sup>6</sup> Life insurers were also significant and expanding home mortgage lenders in the U.S. until 1970, with a market share about equal to that of commercial banks. Thrift institutions were the single largest lender group through 1970.

<sup>7</sup> The Federal Home Loan Banks are also government sponsored enterprises, but in this paper GSE refers only to Fannie Mae and Freddie Mac

The most knowledgeable and risk tolerant investors purchased the junior tranche, thus taking on the first-loss position, and were compensated with an appropriately higher interest rate.

Fannie Mae and Freddie Mac, as government sponsored enterprises (GSEs), operated two separate but complementary business activities. The first was to retain on-balance-sheet mortgage portfolios. The combined Fannie and Freddie retained portfolio share of total home mortgages is shown in Figure 1. Through 1990, the portfolios were primarily invested in whole mortgages and never exceeded a 6 percent market share. After that, the GSEs greatly expanded their MBS holdings—purchasing both their own agency MBS and PLS MBS positions. They thus reached a market share of 19% in 2000 before falling back to 12% in 2009.<sup>8</sup>

The second GSE activity was to issue guaranteed MBS that were primarily sold to third-party capital market investors. This class of mortgage holders are shown in Figure 1 as “market investors,” which is computed as the residual category. Their growth begins in 1980 and is almost entirely represented by MBS positions, both agency MBS and PLS MBS. This investor category includes mutual funds, REITs, property and life insurers, pension and retirement funds, and foreign investors. The list demonstrates how mortgage-backed securitization achieved the benefit of expanding the class of investors far beyond the depositories who, otherwise, had to hold directly all the whole home mortgages they originated. By 2009, these market investors were holding 46 percent of all U.S. home mortgages, almost entirely as MBS positions.

The key fact of Figure 1 is the dominance by 2009 of market investors and commercial banks as holders of all U.S. whole mortgages and MBS—a combined 88 percent market share, while the retained mortgage portfolios of Fannie Mae and Freddie Mac represent only 12 percent of the total. The implication is that a gradual run off of the GSE mortgage portfolios—over at least a 7-

---

<sup>8</sup> The decline in the GSE share after 2000 is primarily the result of an accounting scandal at both firm that became public in 2002, the resulting restrictions placed on the firms by their regulator, and finally the effects of the subprime boom and crash.

year period under the proposal here--should be accomplished without any major stress in the flow of funds for U.S. mortgages. That is, either the market investors or the commercial banks should have no serious problem replacing the 12 percentage point market share left by terminating the GSEs.<sup>9</sup> For example, as shown below, in the European mortgage market commercial banks hold the majority of home mortgages, funded with either deposits or, to a significant degree, by issuing covered bonds to capital market investors. Covered bonds, in fact, are a form of securitization, and I discuss below their possible future role in the U.S. mortgage market.

In summary, all mortgage investments start in the capital markets, whether through bank depositors, covered bonds, the GSE retained portfolios, or direct MBS investments, and a restriction in one channel is generally and easily offset by growth in the other channels. In this sense, elimination of the GSE on balance-sheet portfolios is a minor concern.

## **2.C The Performance of the U.S. Mortgage Market Without GSEs**

While abolishing the GSEs creates no significant flow of funds issues, the quality of the mortgage and MBS assets that will be available in the market remains a question. At year-end 2009, there were \$6.2 billion in home mortgage MBS outstanding, of which \$3.9 billion, or 62 percent of the total were issued by the two GSEs. Most investors in these GSE MBS relied on the associated implicit Treasury guarantee, and thus ignored the default risk embedded in the underlying mortgages. Following the GSE Conservatorships in September 2008, the implicit guarantees became “effective”, so these investors are basically home free. Under the proposal here, however, these assets will mature and new MBS will be issued by private firms and without any form of government guarantee. What will happen then? The answer comes in two parts.

---

<sup>9</sup> In particular, as the GSE retained mortgage portfolios run off, so will the debt that funded these portfolios. The investors in this debt thus are one example of a set of investors who could replace the GSEs as mortgage holders.

The first part assumes that the quality of U.S. mortgages remains unchanged. In this case, investors will directly face the default risk embedded in these mortgage and will require a higher yield to purchase the MBS securities. Mortgage interest rates in the U.S. will then rise. Most empirical studies indicate that the mortgage interest rates on GSE conforming mortgages were approximately 25 basis points (bps) below the interest rates on equivalent mortgages that could not be acquired or guaranteed by the GSEs. Some recent studies suggest an even lower differential between GSE and private mortgages.<sup>10</sup> Even using the 25 bps spread, however, the amount seems quite minor given that mortgage interest rates commonly fluctuate by full percentage points as the result of macroeconomic shifts in the financial markets. Furthermore, the GSE subsidy came at a huge cost to U.S. taxpayers: I noted earlier that current estimates suggest that the final GSE losses may cost U.S. taxpayers upwards of \$400 billion. Thus even a 25 bps cost seems a low price to pay to avoid all the taxpayer subsidies and costs of maintaining the GSEs.

The second part of the answer is even more optimistic. It reflects the fact that private market lenders and investors will pay much more attention to the quality of new mortgage loans than was their behavior under the GSE-dominated market. The fact is that the GSEs discouraged risk-based pricing in the mortgage market: the GSEs either accepted or rejected the mortgage loans they evaluated. It was basically a pass-fail system. And as most professors can attest, this leads to lower overall performance compared to a system in which superior performance is properly rewarded. A private market system will charge lower mortgage rates on safer mortgages and higher mortgage rates on riskier mortgages. The outcome will be a market with overall safer mortgages, which implies lower overall mortgage interest rates.

---

Notes:						
(1) Unless noted otherwise, the data are all from European Mortgage Federation (2009), an annual fact book that contains comprehensive mortgage and housing market data for the years 1998 to 2009 for 15 Western European countries and the United States.						
(2) Computation based on housing starts where available; all other countries use housing permits.						
(3) The mortgage interest for the European countries is the country's representative variable mortgage rate; see European Mortgage Federation. The U.S. rate is the Freddie Mac 1-year ARM commitment rate.						
(4) The mortgage interest rate spread equals the mortgage interest rate (column 4) relative to the Treasury bill rate of each country from the International Financial Statistics of the International Monetary Fund where available. Many of the Eurozone countries no longer publish independent Treasury bill rates; the French Treasury Bill rate is used as the standard in these cases						

It is, of course, an empirical question whether the shift to safer mortgages will actually dominate the loss of the 25 bps subsidy provided by the GSEs to conforming mortgage borrowers. There is, fortunately, a large and long-standing market place that can provide useful insights into the likely answer: most of the countries of Western Europe have mortgage markets that have operated for many years with minimal government intervention—and certainly without government intervention at the level of the U.S. GSEs. As we will now see, the mortgage interest rates in these countries are lower than those created by the GSE dominated system in the U.S. In fact, we will now see that the performance of the Western European mortgage and housing markets has dominated that of the U.S. on basically all relevant measures.

### **3. Western European Mortgage and Housing Markets**

It has been more than 40 years since the U.S. mortgage markets operated without the significant presence of GSEs, so an immediate question is whether a private market can adequately provide the mortgage origination and investment services required by a large and dynamic housing market? Fortunately, the mortgage markets of Western Europe have operated for decades with limited government intervention and thus provide a ready-made laboratory to observe the efficiency and effectiveness of basically private housing and mortgage markets.<sup>11</sup>

#### **3.A. The Performance of Western European Housing and Mortgage Markets**<sup>12</sup>

Table 1 compares the U.S. and Western European mortgage markets for a range of quantitative attributes from 1998 to 2009 based on a comprehensive data base of housing and mortgage data for fifteen European countries from the European Mortgage Federation (2009).

---

<sup>11</sup> It may seem surprising that the “socialized” countries of Western Europe have limited government interventions in their housing and mortgage markets. One explanation is that such interventions would likely violate the European Union prohibitions against countries using subsidies to provide unfair advantages to local agents and firms.

<sup>12</sup> See European Central Bank (2009) for an extensive review of housing finance in the European Union countries.

Column 1 compares the 2009 owner occupancy rates for the U.S. and European countries. The U.S. value is 67.2 percent, which is just below its peak subprime boom value. It is frequently suggested that the high rate of homeownership is the result of the large U.S. government support of the mortgage market, including the GSEs. It is thus highly revealing that the U.S. rate is just at the median—8<sup>th</sup> out of the 16 developed countries—and precisely equals the average value for the European countries. Furthermore, the lower owner occupancy rates in some of the countries, Germany for example, appear to be the result of cultural preferences rather than government inaction. A full analysis of the determinants of owner occupancy rates across countries should also control for the age distribution of the population, since younger households, and possibly the oldest households, may have lower ownership rates in all countries. Chirui and Jappelli (2003) provide a start in this direction, showing that lower downpayment rates are a significant factor encouraging owner occupancy after controlling for the population age structure in a sample of 14 OECD countries. The U.S. has also generally benefitted from very low downpayment rates, but it still has an average ownership rate, reinforcing the conclusion that the government interventions have been largely ineffective in raising the U.S. home ownership rate relative to its peers.

Column 2 measures the volatility of housing construction activity from 1998 to 2009 based on the coefficient of variation of housing starts as a measure of relative volatility. The U.S. relative volatility is 5<sup>th</sup> highest out of the 16 countries, implying that the government interventions have failed to reduce U.S. housing cycles relative to those in Western Europe.

Column 3 measures the volatility of house price changes based on the standard deviation of the annual house price appreciation from 1998 through 2009. Here the U.S. stands 4<sup>th</sup>, meaning the country has faced a relatively high rate of house price volatility. This negative result is all the

more significant because the U.S. is far larger than any of the individual European countries, and thus the benefits of regional diversification should have lowered the observed U.S. volatility.

Column 4 compares the level of mortgage interest rates in Western Europe and the U.S., using “representative variable mortgage rates” for Europe and the Freddie Mac 1-year ARM commitment rate for the U.S.<sup>13</sup> The column shows that the U.S. has the sixth highest average mortgage interest rate from 1998 to 2009, and exceeds the Western European average by 22 basis points. Since overall interest rates also vary across countries, as a further test, column 5 shows the average spread between the mortgage rate and the Treasury bill rate for each country. The U.S. ranks fifth highest based on the spread and exceeds the Western European average by 39 basis points. Of course, mortgage contract terms, such as downpayment requirements, also vary by country, and the resulting variations in mortgage risk will be reflected in the mortgage rates.<sup>14</sup> Below, I return to the question of underwriting standards in a reformed U.S mortgage market. For now, the primary conclusion is that U.S. government mortgage market interventions have failed to improve access to homeownership through the channel of lower mortgage rates.<sup>15</sup>

Finally, Column 6 shows the 2009 ratio of home mortgages outstanding to each country’s annual GDP, a standard measure of the depth of a country’s mortgage market. The U.S. ratio is 81.4% which puts it 5<sup>th</sup> within this group of 16 developed economies. A relatively high U.S. result is not surprising given the large mortgage subsidies provided through the GSEs and other

---

<sup>13</sup> Variable mortgage rates are the only data systematically available for Europe over the required time span and for all the countries; see European Mortgage Federation (2009) for the detailed definitions. The Freddie Mac 1-year ARM rate was chosen as the closest equivalent for the U.S.

<sup>14</sup> For example, Neuteboom (2004) has computed the *net interest rate*—the nominal interest rate adjusted for contractual, cost, and subsidy factors—for a range of European countries. Austria, Ireland, and Spain are the only countries for which the net interest rate is significantly higher than the nominal rate—about 100 basis points in each country. It is unclear how U.S. mortgage rates would fare under this criterion.

<sup>15</sup> The conclusion of generally higher mortgage interest rates in the United States is confirmed in European Central Bank (2009), p. 71.

channels. It is noteworthy, moreover, that four Western European countries achieved even higher ratios without substantial government interventions in their mortgage markets.<sup>16</sup>

Mortgage defaults are a remaining and obviously important mortgage market attribute to consider in comparing European and U.S. mortgage markets. Table 2 tabulates the available recent data on mortgages in arrears, or impaired, or in foreclosure for the available Western European countries as well as the United States. The most dramatic difference between Western Europe and the U.S. is in the foreclosure rate. The U.S. foreclosure rate at year-end 2009 is 4.58% for all mortgages and 3.31% for prime mortgages (not to mention 15.58% for subprime loans). In contrast, Spain and the U.K. are two of the most distressed countries, but their foreclosure rates are 0.24% and 0.19% respectively. Ireland is the other Western European country currently facing serious mortgage distress as shown by its high rate of mortgage arrears in Table 2. Ginsberg and Turner (2010), however, report that actual foreclosure rates in Ireland remain very low. More generally, the European Central Bank (2009, p. 73) states, "...borrowers in Euro area countries do not generally have major incentives to default on a mortgage, since they remain personally liable for any difference between the value of the property and the amount of the loan". The clear conclusion is that European mortgage default activity is very benign compared with the United States..

The overall conclusion has to be that Western European mortgage and housing markets have outperformed the U.S. markets over the full range of available measures. Although data are not provided here, a similar conclusion would hold for the Australian and Canadian mortgage markets. The next section considers the factors that created the superior performance in Europe.

---

<sup>16</sup> Warnock and Warnock (2008) and Renaud (2009) note that significant depth for a country's mortgage market requires a sound legal and accounting infrastructure. All the countries in Table 1 have such an infrastructure, but creating it is of fundamental importance if developing countries are also to create significant mortgage markets.

	≥ 3 Month Arrears %	Impaired or Doubtful %	Foreclosures	Year

### **3.B The Unique Features of Western European Mortgage Markets**<sup>17</sup>

What features of European mortgages or mortgage markets have created this outstanding performance? This section considers a range of possible answers: government intervention, MBS versus covered bond systems, and mortgage contract terms and conditions.

#### **3.B. 1 Government Intervention**<sup>18</sup>

Given the multi-dimensional structure of government interventions in mortgage markets, no single metric can provide a complete comparison of the Western European countries with the United States. It is possible, however, to distinguish at least three separate channels for government intervention and to make comparisons one channel at a time. The channels are:

<sup>17</sup> Few studies have provided quantified and institutional comparisons of mortgage systems among the developed countries of the world. Boleat (1985) provides an early, unique, and book-length description of housing finance systems in developed and developing countries around the world. Diamond and Lea (1992) dedicate a full issue of the *Journal of Housing Research* to country studies and a statistical comparison of the efficiency of alternative mortgage market systems. The consulting firm Mercer Oliver Wyman has participated in two studies of the European mortgage markets, Mercer Oliver Wyman (2003, 2005). Most recently, Andre (2010) provides an overview of OECD housing and mortgage markets.

<sup>18</sup> Mercer Oliver Wyman (2003 and 2005) provide good overviews of European government interventions—including subsidies, taxation, and regulation—for the mortgage markets.

- 1) Government support for low-income mortgage borrowers;
- 2) Direct purchases/guarantees of middle-market mortgages by government sponsored entities;
- 3) Indirect government mortgage market support.

We shall see that the level of U.S. government support is at least average, and generally ranks at the top. Greater government support thus does not explain the superior European performance.

1) Support for Low-Income Borrowers. The U.S. mortgage reform proposal under consideration here continues the existing FHA and HUD programs that provide mortgage and housing market support for lower income families. Furthermore, it appears that the U.S. and the Western European countries carry out a similar range of programs in support of lower-income households. The conclusion is that government programs in support of lower-income borrowers are not a differentiating factor with regard to the performance of the European mortgage markets.

2) Purchases and Guarantees by GSEs. No European government entity approaches the dominant role of the GSEs in the U.S. mortgage market. In the absence of GSEs, almost all Western European mortgage lending is carried out privately by banks, primarily funded by bank deposits or covered bonds.

Indirect Government Support. Governments provide indirect support for the mortgage market using indirect tax and subsidy instruments. While countries vary widely in the extent and form of such support, the U.S. usage is certainly above average, if not at the top of the list. The most significant and visible program is the deductibility of mortgage interest for the personal income tax. The U.S. appears to allow the most complete deductions, while the U.K.--as a primary example—allows no deduction at all.<sup>19</sup> Another unique U.S. tax benefit is the deductibility of state property taxes from the U.S. federal income tax.

---

<sup>19</sup> European Central Bank (2009), p. 84, provides a detailed description of the income tax benefits afforded mortgage finance in a large number of European Union countries.

As a summary of the comparative role of government sponsored enterprises in Europe and the U.S. it is useful to consider the conclusion of Coles and Hardt (2000, p. 778), the latter author being the Secretary General of the European Mortgage Federation at the time:

*“There is no national or European government agency to help lender funds their loans. Mortgage loans have to be funded on the basis of the financial strength of banks or the intrinsic quality of the securities. EU Law (Article 87 and 88 of the EC treaty) outlaws state aid in the form of guarantees as there may be an element of competitive distortion.*

The overall conclusion has to be that the strong performance of Western European housing and mortgage markets has been achieved with decidedly less government intervention than the U.S. The analysis thus continues by looking at two other factors that may be responsible for the success in Western European housing and mortgage market performance.

<b>Table 3: 2009 Ratio Covered Bonds to Residential Mortgages Outstanding</b>

### **3.B.2 Covered Bonds versus Mortgage-Backed Securitization**

European mortgage markets use relatively little mortgage-backed securitization, but covered bonds are a significant factor and play a similar role. In particular, MBS in the U.S. and covered bonds in Europe carry out the same financial function of linking bank lenders with the capital market investors who are the ultimate source of mortgage market funding. Table 3 shows the ratios of covered bonds to residential mortgages outstanding for the same set of Western European countries covered in Table 1. While most of the countries use covered bonds to fund from 10 to 20 percent of their mortgages, covered bonds dominate in 3 countries, Denmark (100%), Sweden (57%) and Spain (50%). Tests for statistical correlations indicate no significant relationships between the covered bond use in Table 3 and the mortgage market performance in Table 1.<sup>20</sup>

In comparing the U.S. and European systems, it is noteworthy that MBS investors look only to the mortgage collateral to protect against credit losses, whereas covered bond investors receive a bank guarantee as well as the housing collateral. On the other hand, covered bonds are issued as a single-class obligation, whereas MBS use their multi-class structured format to allocate the primary credit risk to the most junior tranche. The implication is that the MBS system is better able to handle relatively risky mortgages by allocating the risk of the junior tranche to more knowledgeable and risk tolerant investors. Covered bonds, in contrast, are generally backed by very high quality mortgages, including the associated contractual and regulatory requirements.

The conclusion is that a covered bond system is most effective with relatively safe underlying mortgages, whereas securitization is most valuable when the mortgages contain significant credit risk. Thus both systems have adapted to the nature of the underlying mortgages.

---

<sup>20</sup> Covered bonds are also backed by local government loans in some of these countries, but those bonds are not included in Table 3.

### **3.C Western European Mortgage Market Success: Safe Mortgages**

Mortgage contract features and underwriting standards are the one remaining topic for comparison between European and U.S. mortgage markets. The U.S. is renowned for offering a wide menu of mortgage choice. It turns out, however, that European countries also offer a wide range of mortgage contracts, albeit with more of the variation occurring across countries than within each country. This section discusses three key mortgage attributes that have differentiated U.S. and Western European mortgages

- Fixed-rate versus adjustable rate mortgages;
- Government regulation prohibiting prepayment penalties;
- Government regulations prohibiting or restricting lender recourse to the borrower's assets as well as the property in case of default;

#### **Fixed Rate versus Adjustable Rate Mortgages**

European countries historically specialized in either fixed-rate mortgages (FRMs) or adjustable rate mortgages (ARMS). For example, the U.K. has long emphasized ARMs, whereas Denmark used primarily FRMs. The trend throughout Europe, however, is to offer a greater menu of contract options, and it appears that both ARMs and FRMs are now available in most countries. For the U.S., a common view is that the GSEs are critical for the provision of FRMs in the United States, but the facts appear to be quite the opposite. First, GSE MBS impose 100% of the interest rate risk on the third-party investors. Second, GSE MBS generally allow free prepayment options for the borrowers, thus accentuating the interest rate risk imposed on the investors. Neither of these features promote FRMs. Indeed, the U.S. ARM share has reached 35% during at least 3 separate episodes over the last 15 year, while the ARM share in the European Union is about 40%; see Krainer (2010) and European Central Bank (2009). Finally,

the availability of FRMs in most European countries, and the dominance of FRMs in several European countries, is a final demonstration that GSEs are not at all essential for FRM contracts.

### **Government Regulations Prohibiting Prepayment Penalties**

Some U.S. states restrict the ability of residential mortgage lenders to impose prepayment penalties on their mortgage contracts. In addition, the GSEs have always resisted acquiring mortgages with prepayment penalties, in part as a simple way to standardize their MBS. This contrasts with the U.S. market for commercial mortgages, where prepayment penalties in the form of yield maintenance or defeasance are standard. European residential mortgage contracts also regularly require significant prepayment penalties, very much like the penalties required on U.S. commercial mortgages; see Mercer Oliver Wyman (2005). The absence of prepayment penalties on standard U.S. FRMs is estimated to add approximately 50 basis points to the mortgage interest rate. It thus appears that prepayment penalties are at least one factor that has contributed to the superior performance of the European mortgage markets. Private mortgage markets in the U.S would thus have the potential to provide U.S. mortgage borrowers with a comparable opportunity to obtain lower mortgage rates if they are willing to accept the penalty costs if and when they prepay a mortgage.

### **Recourse and Limited Mortgage Defaults**

Recourse and limited mortgage defaults are perhaps the most important distinction between U.S. and Western European mortgage contracts. In the U.S., recourse varies across the states, and even where it is allowed, it is rarely applied; see Ghent and Kudlyak (2009). Recourse is rarely applied because a bank must satisfy the strong U.S. consumer protection rules before it can obtain a recourse judgment, and consumers always have the option to apply for a relatively easy bankruptcy. The result is that recourse is not an important safeguard for U.S. mortgage

investors. In Europe, in contrast, recourse is standard and enforcement is firm on most European mortgage contracts.<sup>21</sup> The result is that European lenders, borrowers, and governments act in their mutual interest to create safe mortgages. The outcome is that even in the worst conditions of falling home prices, default rates on European mortgages remain remarkably low from a U.S. perspective. Furthermore, this benefit is obtained without any apparent loss in European mortgage market performance as shown in Table 1.

#### **4. The Likely Structure and Performance of a Private U.S. Mortgage Market**

By combining information from the above case studies of fifteen European counties with the unique features of the U.S. housing and mortgage markets, it is possible to develop a view of the likely structure and performance of a private U.S. mortgage market. Of course, it is recognized that forthcoming regulatory rules and restrictions may either facilitate or rule out certain features, so the view put forth here is necessarily conditional on a projection of future policy.

As developed earlier in the paper, the fundamental features of a mortgage market are described by the mortgage origination, contract design and underwriting, and final investment functions. I use those features as the framework to describe the changes that can be expected as the U.S. mortgage shifts from a GSE dominated to a private institution dominated market.

(1) Mortgage Originations. U.S. mortgages have always been originated by private firms and banks, and this will surely continue in the absence of the GSEs.

(2) Contract Design and Underwriting. The absence of the GSEs will have a variety of fundamental impacts on contract design and underwriting. First, a private market will provide a much greater range of contract menu choices. The GSEs focused on creating a single standardized mortgage contract, the 30-year, fixed payment, fixed-rate, mortgage with no

---

<sup>21</sup> European Mortgage Federation (2007) describes the mortgage collateral rules and recourse across all of the Western European countries.

prepayment penalties and effectively no recourse to borrower assets beyond the housing collateral. While private lenders did create a range of alternative mortgages, including ARMS, Jumbos, and the like, they were always swimming upstream against the subsidized GSEs.

Without the GSE obstacle, I expect the market will provide greatly expanded choices, in effect a menu: fixed-rate versus adjustable-rate, prepayment penalties or not, recourse or not, and so on. A lower mortgage rate will result when the choice benefits the lender, a higher rate will result when the choice benefits only the borrower. Each borrower will make the decisions based on his/her individual circumstances. Of course, very complete and accessible disclosures of the terms and conditions of these mortgages is required if borrowers are to make informed decisions. The July 2008 expansion of the Truth in Lending regulations by the Federal Reserve (2008) already ensures a great deal of this disclosure, and I fully support further expansion to fill in any missing parts. The key principle is that informed borrowers will make good decisions as long as a competitive mortgage market provides a full menu with fair prices.

I expect the outcome of this process will be a U.S. mortgage market in which the mortgages are intrinsically safer, with default and foreclosure outcomes that will more closely resemble the European markets than the recent U.S. subprime experiences. The fact is that mortgage default is incredibly costly to all parties: the lenders and investors face the legal costs of foreclosure and the need to sell properties under distressed conditions, the borrowers lose their homes and credit ratings, and the government is then expected to fix the problem after the fact. A key virtue of a private mortgage market is that both risky and safe mortgages will be originated, but the risky contracts will pay the full price of their risk, and the safe mortgages will realize the full benefits of their safety. Almost surely, the end result will be decidedly safer mortgages in the U.S.

(3) Mortgage Investors. On the surface, the changes for mortgage investors will be minor. The GSEs hold approximately 12 percent of all U.S. whole home mortgages and MBS, and this share will be readily taken up by the depository institutions and capital market investors. At a deeper level, however, the changes will be more substantive. The market will determine who holds the new mortgages: depository institution mortgage portfolios can be funded with deposits or with covered bonds, or they can be sold to third-party investors through traditional securitization. The preferred outcome will depend to an important degree on the quality of the underlying mortgages. Mortgage pools of very high quality mortgages may well be retained by the depository lenders and funded with either deposits or covered bonds. Mortgage pools of riskier mortgage will more likely be securitized, taking advantage of structured finance to allocate the first-loss risk among the most knowledgeable and risk tolerant investors.

It is not always recognized that over the last 100 years of U.S. (and I would say world) finance, the demand for virtually risk-free investments has generally exceeded the readily available supply. A large payoff was thus available to any entrepreneur who could expand the supply of AAA investments. In fact, the demand for such securities was a major force leading to the creation of the senior and super senior AAA tranche of the subprime MBS and CDO securitizations. Alas, these senior and super senior securities turned out to be nowhere as safe as advertised--wine from water is not easy. But the high demand for AAA investments persists today, perhaps even more than ever, and truly high-quality mortgages can become a very important part of the solution, as backing for either AAA-rated covered bonds or senior MBS tranche. The mortgage markets and the capital markets will both benefit.

(4) Further Features. The recreation of the U.S. mortgage market without the GSEs will surely motivate a variety of renewed activities and new innovations. Some areas of renewed activity

can be anticipated. For example, it is likely there will be a continuing role for private mortgage insurance (PMI) in the U.S. mortgage market. Although the GSEs became the major client of the PMI industry, in fact the modern U.S. private mortgage insurance existed and expanded well before the GSEs became important. More generally, a key benefit of a private mortgage market is that the market itself will test and evaluate the available proposed innovations, then implement the successes and discard the failures. And this activity will all occur without taxpayer costs.

(5) Regulatory Requirements. While I expect a private mortgage market will generally operate in a safe and stable fashion, just as it has in Western Europe, a critical role for regulation and government oversight definitely remains. I have already noted that the FHA and HUD programs continue as part of my proposal. I have also noted that the borrower protections and full disclosures under the Truth in Lending Act and similar statutes are critical. I now add to this list the need for expanded regulatory oversight of the depository institutions in regard to all their activities as mortgage originators, servicers, investors, and covered bond issuers. There are two reasons for my emphasis on such depository regulation: (1) deficient bank regulation was a major source of the subprime crisis and this must be fixed; (2) a private mortgage market will likely channel a greater volume of mortgage lending, investing, and securitizing through the banking system, and given that taxpayers backstop the system through the government's deposit insurance, it is critical that the taxpayer's interests be protected by prudent regulation.

## **5. Alternative Proposals**

Discussions and proposals to reform the U.S. mortgage markets have been offered since at least 2008 as the full dimensions of the GSE crash became evident. For example, Federal Reserve Chairman Ben Bernanke (2008) provided an early call for action, including a taxonomy of alternatives ranging from a completely private market to recreating the GSEs. The

Government Accounting Office (2009) and Congressional Budget office (2010) have followed with a similar taxonomy, including factual comments on the alternatives. Some of the earlier ideas, such as a “public utility model” and a breakup of the GSEs into a large number of small units, seem not to have made the first cut.

The most evident proposal today, other than a private market, is to have the government provide a fail-safe guarantee, in some fashion, on all MBS that are based on conforming mortgages. The proposal thus replaces the government guarantee of the GSEs with a direct guarantee on all conforming MBS. In effect, the government will be backing most middle-income mortgages in the United States. Specific versions are available from Acharya, Richardson Van Nieuwerburgh, and White (2011), the Center for American Progress (2010), Ellen, Tye, and Willis (2010), Hancock and Passmore (2010). While the plans differ in details and specificity, a composite can be summarized:

- 1) The plans anticipate government regulations will set the underwriting standards that must be met by all mortgages that underlie the qualifying MBS. The plans also generally anticipate quite high underwriting standards for the qualifying mortgages.
- 2) Investors in the qualifying MBS will be protected from all default risk by a combination of private capital and government guarantee. The government guarantee component is considered essential.
- 3) Risk-based insurance premia will be paid to the private capital and the government as compensation for the risk they bear.

For simplicity, I will refer to this structure as the “government insurance proposal”.

The insurance proposal is clearly preferable to any plan that would recreate the GSEs, since the government would set the underwriting standards and be compensated for the risk it bears.

The key issues are (1) can the government carry out this activity effectively and efficiently, and (2) is the government's role important for a well-functioning U.S. mortgage market. My answer to both questions is negative, which I take up in turn.

Regarding the first question, the government is generally terribly ineffective in managing insurance programs. The fundamental problem is that the government is unable to enforce any rational risk-based pricing (meaning that greater risks should pay appropriately larger premiums). The actual outcome for government insurance is almost always that the premiums are set at the level appropriate only for the safest risks. The political reality is that it is very difficult for a government program to impose higher premiums on riskier policyholders. For the same reason, it is very difficult for a government program to set high underwriting standards that therefore exclude many borrowers from the government program.

These features of government insurance programs have two further negative effects. First, by subsidizing the riskier participants, the government actually encourages these participants to put themselves in harm's way. Second, sooner or later, the riskier pool will create large losses, and the taxpayers will pay the costs. A case study of this negative aspect of government insurance is the National Flood Insurance Program. While for many years it appeared to break even—with premiums covering losses—it turned out that no reserves had been accumulated for the “big one”, with the result that the losses created by Katrina required a taxpayer bailout on the order of \$22 billion. Further discussion of failed government insurance programs is provided in Jaffee and Russell (2006).

The answer to the second question is that government insurance is simply not needed. Most Western European mortgage markets operate without any direct government guarantee, and I see no evidence that this has impeded their performance. Furthermore, the U.S. already has two

forms of mortgage insurance programs that can, and would, be expanded as needed. The first is the private mortgage insurance that already exists, including a well structured regulatory regime. It is likely that in the normal course certain classes of mortgages should be insured, and the PMI industry should be willing and able to do that. The second is the government's FHA program for insuring mortgages for lower-income and other socially worthy borrowers. The FHA program has existed since 1934, it operates under a requirement that its premiums and charges cover its expected losses on an actuarial basis, and it has never required a government bailout. The FHA program could be rapidly expanded if it did occur that the private markets were failing to provide adequate service to the U.S. mortgage market. An example could be a future financial crisis—whether originating in the housing market or elsewhere in the economy--in which the supply of private capital to the mortgage market is disrupted. The FHA could then be empowered to expand its mortgage guarantee to a wider band of mortgage borrowers. Indeed, this is exactly what is occurring currently, as the FHA takes on guarantees for some modified mortgages under the government's current loan modification programs.

## **6. Summary and Conclusions**

This paper has developed and evaluated a proposal to reform the U.S. mortgage system on private market principles and without any form of government sponsored enterprises. The proposal is implemented through the simple process of reducing the GSE conforming loan limit by, say, \$100,000 annually, with the result that the GSEs will cease to operate after about seven years. The transition process will be smooth, anticipated by the private markets, and allow for a government reaction if it fails to proceed as expected. The proposal also advocates continuing the current FHA and HUD programs in support of lower-income families.

The primary issue facing the proposal is actually very direct: will a private market provide the stability and access to mortgage credit required by U.S. homebuyers. The paper provides a fully affirmative answer based on two sets of evidence. First, the GSEs have actually played no role in originating U.S. mortgages and a relatively minor role as investors in these mortgages. Thus it will not be difficult for the private markets—principally depository institutions and capital market investors—to replace the GSEs. Secondly, Western Europe provides a very important case study of how well mortgage markets do operate in the absence of any significant government intervention.

The analysis in the paper further outlines the likely structure of a U.S. mortgage market that operates without GSEs. Mortgage origination activity will be unchanged from the current system, since originations are already carried out by only private market entities. Mortgage investing will also continue to be dominated by the two largest holders, depository institutions and capital market investors. Depository institutions will continue to hold a significant amount of whole mortgages in their portfolios, and the capital market investor portfolios will continue to be dominated by mortgage-backed securities. It is also likely that covered bonds will come to play a more important role in the U.S. market, as depository institutions fund some of their mortgage portfolios by issuing secured debt to capital market investors. In this fashion, the market should readily absorb the 12 percent market share vacated by the departing GSEs.

The most important changes in the U.S. mortgage market are likely to occur in the types of mortgage contracts that are offered, and the underwriting standards that are imposed on the borrowers. A private mortgage market is likely to provide borrowers with an expanded menu of choices, including, as examples, such features as (1) fixed-rate versus adjustable rate loans, (2) contracts with or without prepayment penalties, and (3) contracts with or without recourse to the

borrower's non-housing assets. At the same time, borrowers will face risk-based pricing: borrowers who are intrinsically risky or who chose riskier mortgages will face appropriately higher mortgage rates, while safer borrowers and safer contracts will be rewarded with lower mortgage rates. Given this direct incentive, borrowers will overall choose safer mortgages, thus reducing the average mortgage interest rate. To a first approximation, it appears that U.S. mortgage interest rates will be unchanged under the proposed system, since the benefits of safer mortgages will roughly offset the loss of the previously available GSE subsidy. Of course, the proposal is a complete win for U.S. taxpayers, since the taxpayer costs of the GSE subsidy far exceeded all of its possible benefits.
